01 Real Atlas Map

02 Executive Signal Hydraulic exposure / Railway crossing

For railway crossing interventions in the selected province, ARCUS indicates that preliminary attention should focus on track continuity and related checks because the dominant indicator is hydraulic exposure. This is a province-level screening signal and must be translated into site-specific checks by qualified professionals.

3 KEY FINDINGS Why it matters

- Hydraulic exposure is the dominant Step 3 exposure signal (97 / 100).
- P1 Castellamonte, P2 Ala di Stura, P3 Ala di Stura are the map-referenced priority precedents.
- Railway crossing changes the operational reading: Track continuity; railway embankment stability; hydraulic openings.

5 NEXT CHECKS What to do next

- Identify railway sections intersecting flood-prone or hydraulic-sensitive corridors.
- Review hydraulic openings, culverts and bridge supports for preliminary exposure.
- Consider operational continuity and inspection access during hydraulic events.
- Translate province-level screening into site-specific checks by qualified professionals.
- Compare planned intervention assumptions with P1/P2/P3 historical precedents.

LIMITATIONS Use correctly

- Province-level screening only, not design scale.
- ARCUS does not certify structural safety or asset condition.
- CSV and GeoJSON exports remain the detailed data package.

TOP DATA TO REQUEST

- Railway alignment
- Embankment geometry
- Hydraulic opening data
